THEN AND NOW

Highlights of Connecticut Vital Statistics 100 Years Ago and Today

Statistic or event	1895	1995
Population (estimated)	816,712	3,274,662
Live births	19,931	44,388
Rate (per 1,000 population)	24.4	13.6
Deaths	14,546	29,438
Rate ^b (per 1,000 population)	17.8	9.0
Fetal deaths	825	285
Rate ^b (per 1,000 live births)	23.1	6.4
Infant deaths (<1 year old)	3,014	322
Rate (per 1,000 live births)	151.2	7.3
Marriages	6,623	22,612
Rate (persons per 1,000 population)	16.2	13.8
Divorces	417	10,656
Rate (persons per 1,000 population)	1.0	6.5
Ratio of divorces to marriages	1:15.9	1:2.1

^a The 1895 Registration Report did not distinguish between events by residence and occurrence. The 1995 figures are by residence.

^b Death rates are expressed as "crude rates."

^c Fetal deaths were called "still births" in the 1895 Registration Report.

Leading Causes of Death: 1895 and 1995

1895^a				1995

^a From Connecticut's *Registration Report for the Year Ending December 31, 1895*, Diagram E, Table VI, and Table XI. Deaths from other causes of interest include homicide (8), suicide (107), typhoid fever (259), measles (26), syphilis (20), chronic alcoholism (41), breast cancer (62), starvation (4), kicked by horse (1), run over by wagon (4), electric car accidents (5), insanity (56), bedsores (1), and rabies (2).

^b Pulmonary tuberculosis.

^c Cerebrovascular disease; stroke.

^d Accidental deaths in 1895 included drowning (100), falling (59), burns and scalds (68), asphyxia by illuminating gas (7), and crushed by an elevator (2).

^e In 1895 "old age" began at 50 years.

^f Chronic nephritis.

^g COPD = Chronic obstructive pulmonary disease (chronic bronchitis, emphysema, etc.).

^h Nephritis, nephrotic syndrome, and nephrosis.

ⁱ Rates are crude death rates per 100,000 population

1995 VITAL STATISTICS

INTRODUCTION

The *Registration Report* is a statistical summary of vital events for the State of Connecticut, published each year by the Office of Policy, Planning, and Evaluation at the Connecticut Department of Public Health. The series began with the report of 1848 and has been published annually since then, except for 1852. Connecticut's vital statistics data base contains records pertaining to five types of events: births, deaths, fetal deaths, marriages, and divorces.

General Comments

Completeness of Registration

The statistics presented in the *Registration Report* reflect not only vital events that occur in Connecticut but also those concerning Connecticut residents that occur in other states and Canada. The Connecticut Department of Public Health reciprocates with every other state in the U.S. and the provinces of Canada in exchanging copies of birth and death records for non-residents. Registration of births in Connecticut is essentially 100% complete, and there is virtually no under-reporting of deaths. Because there is no interstate transfer of marriage, divorce, or fetal death records, however, it is not possible to determine the completeness of registration of these events for Connecticut residents.

Reporting by Local Health Districts

Summary statistics are reported for multi-town Local Health Districts in several tables. Summations for local health districts may enable local health agencies to better understand and serve their resident populations. The composition of the respective health districts reflects membership as of June 8, 1995 (see listing in Appendix II).

Comparison of Rates and Percentages

Rates were calculated using the equations given in Appendix I. Caution should be used in drawing conclusions based on rates or percentages that were calculated from small numbers of events. Due to the variability of these figures, the data tables do not contain rates or percentages for less than five related events. *Percentages based on birth data do not include records from which information about the characteristic of interest was missing.* The term "unknown" as used in this report includes both "missing" responses (no code entered) and responses coded as "unknown."

Births

Reporting of Mother's Race and Ethnicity for Births

Beginning with the 1991 *Registration Report*, the mother's race and ethnicity classifications for births consist of three mutually exclusive groups: white non-Hispanic; black non-

Hispanic; and Hispanic (of any race).* These categories are consistent with those used by the National Center for Health Statistics, Centers for Disease Prevention and Control, thus allowing Connecticut statistics to be compared with national figures. Birth tabulations for the eight Connecticut towns with 1,000 or more births, based on the mother's race classification used before 1991, are available upon request (see below for address).

Inclusion of “Presumptive Marital Status”

“Presumptive marital status” is included in Table 3 of this report for historical reasons, even though its validity is limited [1]. Connecticut law has forbidden reference to illegitimacy, birth in or out of wedlock, or marital status on the birth certificate for more than 50 years; nonetheless, “illegitimate” or “out-of-wedlock” births have always been included in the State’s vital statistics reports. From 1947-1988 such births were inferred from the absence of a father’s name on the birth record, and since 1989 the mother’s presumptive marital status has been determined by matching of surnames. Even in early registration reports dating to the 1800’s, numbers of illegitimate births were characterized as “approximations to the real facts.” Current plans to modify the birth record will enable reporting of actual rather than presumptive marital status beginning in 1998.

Qualification Regarding 1995 Birth Data

Due to late closure on a few birth records, the total birth count in this report is three less than the number in the final revised 1995 file. This difference has no substantive impact on the findings reported. It will, however, be important to readers who use this report to validate summary counts derived from the revised tape.**

* Table 2B is an exception to the general use of the composite race/ethnicity in the classification of birth data. Birth figures for this table were tabulated with separate race and ethnicity classifications (i.e., *white*, *black*, and *Hispanic*). This classification structure was retained to enable direct comparability with death data, which are given in the same table, and to make it easier for readers to compute mortality rates.

** The total Connecticut resident birth count in this report is 45,459; the number on the revised final tape file is 45,462. The revised file includes four additional records and one deletion, which are identified below.

Revision No.	Revision Type	Town of Residence	State of Occurrence	Sex	Birthweight (grams)
1	Add	Waterbury	CO	F	>2,500
2	Add	Hampton	CO	F	>2,500
3	Add	Durham	GA	F	>2,500
4	Add	Vernon	MA	M	<2,500
5	Delete	Greenwich	CT	M	>2,500

Deaths

Comparability of Cause-of-death Data

The system for classifying cause of death, the *International Classification of Diseases* (ICD), is revised approximately every ten years to reflect changes in medical practices and new medical knowledge. As each ICD revision results in a degree of discontinuity in cause-of-death statistics, a ratio of comparability is used to adjust for classification changes in the revisions. Causes of death in 1995 were coded using the ninth revision of the ICD (known as the ICD-9), which became effective in 1979, and using the *Addendum to the International Classification of Diseases Ninth Revision* for the classification of infection with human immunodeficiency virus.

Marriages and Divorces

The presentation of marriage and divorce information has been made more concise in both the narrative and tables sections of this report.

Additions to the 1995 Registration Report

Table 3 of the *Registration Report* traditionally has contained data on birthweight and prematurity classified with respect to various risk factors. In the 1995 report, two new maternal risk factors, "tobacco use during pregnancy" and "alcohol use during pregnancy," have been added to Table 3. These additions were made possible by improved completeness of their respective fields on Connecticut birth certificates. The new information constitutes an important addition to the existing natality indicators in this report. Both exposures are potentially preventable, associated with significantly increased risk of poor pregnancy outcomes, and relatively common.

Maternal tobacco smoking during pregnancy is associated with a reduced birthweight, premature delivery and risk of spontaneous abortion, and perinatal death [5]. Percentages of low birthweight and premature deliveries were about twice as high among women who smoked as among non-smoking women in 1995. The elevated risk of low birthweight among smokers in Connecticut, coupled with the relatively high prevalence of smoking, suggest that this risk behavior is likely to play a substantial role in poor pregnancy outcomes.

Alcohol consumption by women before and during pregnancy is associated with low birthweight, fetal alcohol syndrome, and, to a lesser extent, preterm delivery [5]. Alcohol use is probably underreported in the Connecticut birth records. Nevertheless, these data can be useful in assessing relative risks at the community level. When compared with national data [5], alcohol use in Connecticut has a consistent pattern of association with poor pregnancy outcomes.

For Further Information

Definitions of the technical terms used in this document are given in the *Glossary* at the end of this report (Appendix III). Supplemental tables containing 1995 town-specific information in the format of Table 8 (Infant Mortality) and Table 9 (Mortality, by Age) also are available. Additional 1995 vital statistics data are included in the *AVSS Advance Natality Report for Connecticut Residents, January-December 1995 Birth Data*. These publications can be obtained from the Connecticut Department of Public Health, Office of Policy, Planning, and Evaluation.

Availability on the Internet

The narrative portions of the 1992 and 1993 *Registration Reports* and the full reports for 1994 and 1995 are available on the internet at the following web site:

<http://www.state.ct.us/dph/reports.html#oppe>

POPULATION DISTRIBUTION

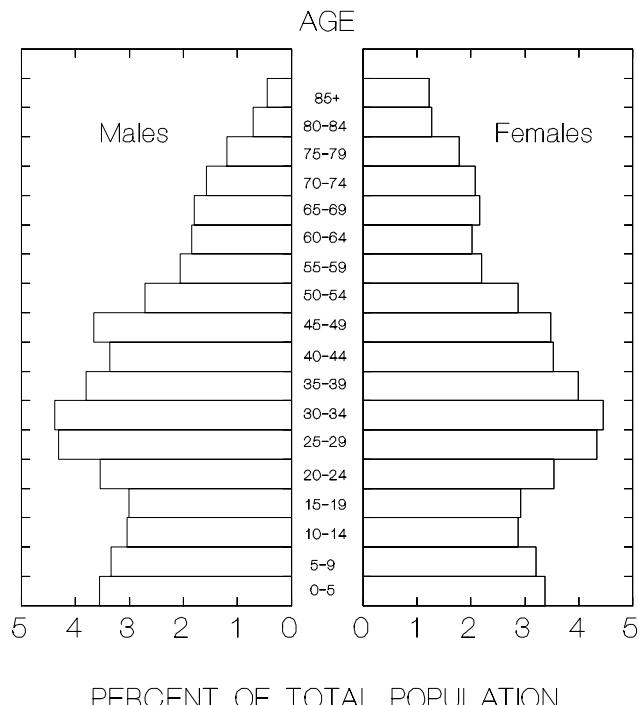

Age and Sex

The estimated July 1, 1995 population of Connecticut was 3,274,662 [2], which is 12,454 (0.4%) lower than the July 1, 1990 census count of 3,287,116 and 589 (0.02%) lower than the 1994 estimate. Of the total population, 1,588,141 (48.5%) were males and 1,686,521 (51.5%) were females. In the age groups from <1 year through 20-24 years, the number of males exceeded that of females. In all subsequent 5-year age cohorts, however, females exceeded males. By ages 75-79, 80-84, and 85+ years, females outnumbered males by ratios of nearly 3:2, 2:1, and 3:1, respectively (Fig. 1, Table 1). These ratios have been about the same since 1989.

Towns

Compared to the 1990 census populations, the 1995 estimated populations were lower in 56 Connecticut towns and higher in 113 towns [3]. Eighteen towns lost 1,000 or more residents, and five towns (Cheshire, Norwalk, Danbury, New Milford and Stamford) grew in population by more than 1,000. New Haven lost the most people (6,818) for the third year in a row, and Stamford gained the most (2,661) for the second consecutive year. For the fourth consecutive year, Mansfield lost the greatest percentage of residents (14.1%), and Canaan had the greatest percentage gain (20.3%). Among the five towns with populations greater than 100,000, the estimated populations of four towns decreased between 1990 and 1995 (New Haven, -5.2%; Bridgeport, -3.4%; Hartford, -2.9%; Waterbury, -1.3%); the estimated population of the fifth town, Stamford, increased by 2.5%.

Figure 1. Percent Population Pyramid, Connecticut, 1995

BIRTHS

Demographic Factors

Town of Residence

The total number of live births to Connecticut residents in 1995 was 44,388. This represents a decrease of 1,407 live births or 3.1% from 1994 and 5,710 (11.4%) from 1990. The birth rate was 13.6 per 1,000 population, down from 14.0 in 1994 and 15.2 in 1990 (Table 2A), marking the fifth consecutive year of decline in both number and rate.

In 1995, the town-specific birth rates ranged from a high of 33.0 per 1,000 population in Canaan (the fourth consecutive year that this town had the highest birth rate in the state) to a low of 4.5 per thousand in North Canaan (the second year in a row for this distinction).

Eight towns (Bridgeport, Danbury, Hartford, New Britain, New Haven, Norwalk, Stamford, and Waterbury) each registered more than 1,000 births during the year; these towns accounted for 30.2% of resident births but only 25.4% of the population in the state (Table 2A). Both the numbers and rates of births in these towns, however, were lower in 1995 than in 1994, with the greatest rate decrease in Hartford--from 18.9 to 17.0 per thousand--representing a drop of 10.1%.

Mother's Race and Ethnicity

Of the 44,388 resident live births, 30,179 were to white non-Hispanic mothers (a decrease of 2.3% from the 1994 number) and 4,915 were to black non-Hispanic mothers (up 3.1%), representing 68.0 % and 11.1% of the total resident births, respectively. There were 5,514 births to mothers of Hispanic origin (an increase of 4.1% from 1994), representing 12.4% of the total number of resident births (Table 3). Race was unknown for 946 births (2.1%, down from 2.6% in 1994), and ethnicity was unknown for 2,412 births (5.4%, down from 7.5%) (Table 2B).

Infant's Sex

Of the total live births, 22,722 (51.2%) were male and 21,666 (48.8%) were female (Table 3).

Place of Delivery

All but 199 (0.4%) of the total resident births occurred in hospitals (Table 3). There were 161 home births, down from 201 in 1994. Home births accounted for eight out of ten non-hospital deliveries (Table 3).

Live Birth Order and Plurality

Of babies delivered in 1995, 37.2% were first-born; 30.0% were second-born, and 20.9% were third-born or more. In the remaining 11.8% of deliveries, the birth order was not known. Of the total births, 1,354 (3.1%) were multiple births (Table 3). The ratio of single to multiple births was 32:1 overall, 30:1 for white non-Hispanics, 38:1 for Hispanics, and 47:1 for black non-Hispanics.

Mother's Presumptive Marital Status

Connecticut law prohibits inclusion of the mother's marital status on birth records; consequently, marital status is inferred by matching the mother's, father's, and child's surnames according to certain criteria [1]. Although this method of assessing marital status is of limited validity, it has been used since 1989, and similar methods of approximation were used for more

than 100 years previously (see *Introduction*). Following these criteria, 13,570 resident births (30.6%, up slightly from 30.4% in 1994) were presumptively to unmarried mothers in 1995 (Table 3). This proportion is about 44% greater than the proportion of births to unmarried women 10 years ago (21.3%) and more than three times greater than the 1970 figure (9.6%).

Mother's Age

Although the total number of live births was lower in 1995 than in 1994, there were increases in the numbers of births to women aged 16, 18, and 19 years, and in the cohorts comprising ages 30-44 years. From 1994 to 1995, the greatest percent decrease in births (24.0%) occurred among 15 year olds (this group had the greatest percent *increase*, 25.3%, between 1993 and 1994), and the greatest increase, 6.4%, occurred in the age 16 group. Mothers in the age range 20 to 34 accounted for 74.9% of all 1995 births (Table 3), down from 76.0% in 1994 and 80.2% in 1990 (Table 3). An additional 16.5% (7,333) of births were to women aged 35⁺ years, up from 15.6% in 1994; of these, 1,039 (2.3% of total births) were to women aged 40 and over.

For the third consecutive year, more births (14,321 or 32.3%) occurred to women aged 30-34 than to women in any other 5-year age cohort. Births to women aged 20-24 and 25-29 accounted for 15.6% and 27.0% of births, respectively, compared to 16.3% and 28.4%, respectively, in 1994. This is noteworthy because it denotes the reversal of an historic trend; for the prior 47 years and possibly longer, women in the age groups 20-24 or 25-29 had accounted for the greatest numbers and proportions of births to Connecticut residents [4].

Teenagers accounted for 3,806 births or 8.6% of resident births (Table 4), up slightly from 3,873 (8.5%) in 1994. Of total births, 3.7% (1,645) were to females under age 18 (down from 3.8% or 1,751 in 1994); these included 87 births to mothers less than 15 years old (Tables 3 and 4). The 1994 figure represented the highest percentage of births to mothers under age 18 since 1982. White non-Hispanics accounted for the majority (78.2%) of births to older mothers (aged 35+) in 1995, whereas 58.2% of teenage mothers were either black non-Hispanic or Hispanic. Of total births to white non-Hispanic, black non-Hispanic, and Hispanic mothers, 4.5%, 19.1%, and 23.1%, respectively, were to females under age 20.

Birth Outcomes and Associated Risk Factors

Low Birthweight

Overall, 3,129 or 7.1% of all births in 1995 were of low birthweight (<2,500 grams) (Table 4), up from 6.9% in 1994. This was the largest proportion of low birthweight births since 1979, when the figure was 7.2%. As was true in the past, the risk of low birthweight delivery was not distributed evenly across all communities (Table 4) or risk groups (Table 3). Variation in low birthweight occurred within categories defined by mother's race/ethnicity, infant's sex, plurality of births, live birth order, mother's presumptive marital status, mother's education, mother's age, initiation and adequacy of prenatal care, tobacco use during pregnancy, alcohol use during pregnancy, and town of residence, as noted below.

Race/Ethnicity

The percentages of low-birthweight deliveries in 1995 to white non-Hispanic, black non-Hispanic, and Hispanic residents were 5.7%, 12.7% and 8.9%, respectively (Tables 3 and 4). These represented slight increases from the 1994 rates for white and black non-Hispanics (5.5% and 12.6%, respectively), and a decrease of 0.1% from the 1994 rate for Hispanics. Black non-Hispanic mothers and Hispanic mothers had 2.2 and 1.4 times the risk of white non-Hispanic mothers, respectively, to deliver low-birthweight babies, and 3.5 and 1.9 times the risk, respectively, for very low birthweight delivery (<1,500 grams), respectively.

Infant's Sex

As in previous years, female babies were somewhat more likely than male babies to have low birthweight (7.6% vs. 6.6%). This was true regardless of the mother's race or ethnicity (Table 3).

Plurality

More than half (51.1%) of all multiple births were low birthweight, compared to only 5.8% of singleton births (Table 3).

Live Birth Order

Infants that were first-born or third-or-more-born in order of live birth were slightly more likely to be of low birthweight (7.5% and 7.6%, respectively). In contrast, only 5.8% of second-born infants had low birthweight (Table 3).

Mother's Presumptive Marital Status

Unmarried mothers [1] were 1.8 times more likely than married mothers to deliver low birthweight babies (10.3% and 5.7%, respectively).

Mother's Education

Mothers with 12 years or less of education had the highest percentage (8.5%) of low-birthweight births (Table 3). Overall, and for each racial/ethnic subgroup, mothers who were college educated and those with post-college education had lower percentages of low-birthweight deliveries (5.8% and 5.7% overall, respectively).

Mother's Age

In general, higher percentages of low birthweight were found among mothers under age 20 and over age 45. Mothers less than 15 years old and more than 44 years old had the highest levels of low birthweight deliveries (20.7% and 28.0%, respectively), whereas women aged 30-34 had the lowest level, 6.4%. Percentages of low-birthweight deliveries were consistently high among black non-Hispanic mothers, and reached double digits in all age groups except <15 years (insufficient data for calculation), 17 years, and 20-24 years (Table 3). Where calculations were possible, percent low birthweight for Hispanics was always higher than for white non-Hispanics and lower than for black non-Hispanics except in the age 17 group.

Initiation of Prenatal Care

The trimester of pregnancy in which women begin prenatal care is a strong indicator of risk of low birthweight. Generally, the later the prenatal care begins, the greater the likelihood of low birthweight deliveries. Women who received no prenatal care were four times more likely than women who began care during the first trimester of pregnancy to deliver low-birthweight babies (26.6% and 6.6%, respectively). Women who began prenatal care after

the first trimester had about a 20% greater likelihood of low birthweight delivery (Tables 3 and 4).

Adequacy of Prenatal Care

Adequacy of prenatal care, as defined by a modified Kessner Index (see Appendix III), is a measure involving the timing of the first prenatal visit, the total number of prenatal visits and the duration of gestation. The highest risk subgroup, inadequate care, had more than three times the frequency of low-birthweight deliveries as the lowest risk subgroup, adequate care (18.3% and 6.0%, respectively), and the intermediate adequacy group had 1.4 times more than the adequate care group (Table 3).

Tobacco Use during Pregnancy

Of women who delivered in 1995, the percent of low birthweight was twice as great for those who used tobacco during pregnancy than for those who did not (12.5% and 6.2%, respectively). In all racial/ethnic groups, the percent low birthweight was substantially higher for mothers who used tobacco than for those who did not, by a factor of about 1.5 to 2.0.

Alcohol Use during Pregnancy

The percent of low birthweight births was more than twice as great for those who used alcohol during pregnancy than for those who did not (14.4% and 6.7%, respectively). This same two-fold elevation in percent low birthweight was found for white non-Hispanic and black non-Hispanic infants. The same comparison could not be made for Hispanic infants, because of the small number of records for this group.

Town of Residence

As in previous years, percent low birthweight varied greatly across communities within Connecticut (Table 4). In the eight towns with 1,000 or more births, there was a two-fold difference between the towns with the lowest and highest percentages (Danbury, 5.7%, down from 7.7% in 1994; and Hartford, 13.4%, up from 12.7%). The percentages of low birthweight deliveries in all the remaining towns in this group except Norwalk (6.4%) exceeded the state rate of 7.1%. They were: New Haven, 10.9%; Bridgeport, 9.0%; Waterbury, 10.8%; Stamford, 7.5%; and New Britain, 9.4%. These towns accounted for 1,274 low-birthweight deliveries, or 40.7% of low birthweight births to Connecticut mothers, but only 30.2% of total resident births.

Premature Births

In 1995, 9.6% of all resident births were premature (<37 weeks of gestation), up from 9.0% in 1994 (Table 3) [8]. Substantial variation occurred within the categories defined by mother's race/ethnicity, infant's sex, place of delivery, plurality, live birth order, mother's presumptive marital status, mother's education, mother's age, initiation of prenatal care, adequacy of prenatal care, and mother's use of tobacco and alcohol during pregnancy. These differences are similar to those noted for low-birthweight deliveries.

Race/Ethnicity

The percentages of premature births by race/ethnicity were: white non-Hispanic, 8.1%; black non-Hispanic, 15.1%; and Hispanic, 12.3% (Table 3). Relative to white non-Hispanics, the risk of preterm delivery was 1.9 times greater for black non-Hispanics and 1.5 times greater for Hispanics.

Infant's Sex

Although more female infants had low birthweight, 11.0% more males than females were born prematurely (10.1% and 9.1% premature, respectively). In 1994, the percent of prematurity was identical for both sexes (9.0%).

Place of Delivery

Premature babies were more likely to be delivered in hospitals (9.6%) than at home (6.9%) (Table 3).

Plurality

Premature birth occurred more than six times more often with multiple births (50.5%) than with singleton births (8.3%) (Table 3).

Live Birth Order

Second-born infants were less likely than first- or third-or-more-born to be premature (8.4%, 9.4%, and 11.1%, respectively) (Table 3).

Mother's Presumptive Marital Status

Among presumptively unmarried women [1], premature delivery occurred 50.6% more often than among married women (12.5% and 8.3%, respectively).

Mother's Education

Premature delivery among mothers who had 12 years or less of education occurred more frequently than among college-educated mothers and post-college-educated mothers (10.9%, 8.5%, and 8.3% prematurity, respectively) (Table 3).

Mother's Age

In all age groups except 25-29 and 30-34 years, the levels of premature delivery exceeded the state level of 9.6% (Table 3). Percentages of prematurity were highest among mothers under age 18 (range, 13.4% to 24.4%) and in the 45+ year group (20.0%). Relative to the age group with the lowest rate of premature deliveries (ages 25-29, 8.7%), the figures for women <15 and 45+ years old were 2.8 and 2.3 times greater, respectively. The rates of premature births to black non-Hispanics and Hispanics were consistently high regardless of age.

Initiation of Prenatal Care

Compared to women who began prenatal care in the first trimester of gestation, the frequency of premature delivery was 3.7 times greater for those who received no prenatal care and 1.7 times greater for those who began prenatal care during the last trimester (8.9%, 32.5%, and 14.7% prematurity, respectively). (See *Glossary* for definition of "trimester of pregnancy.")

Adequacy of Prenatal Care

Premature delivery varied with adequacy of prenatal care, as defined by a modified Kessner Index (Appendix III). Women who received inadequate care were three times more likely to deliver prematurely than were those women who received adequate care (25.6% and 8.5%, respectively) (Table 3).

Tobacco and Alcohol Use during Pregnancy

Women who used tobacco during pregnancy were 1.4 times more likely than those who did not to deliver preterm. Those who used alcohol during pregnancy were 1.5 times more likely to deliver preterm than those who did not.

Births to Teenage Mothers

In 1995, 3,806 or 8.6% of all live resident births were to mothers under the age of 20 years (Table 4), representing a decrease in number but increase in percentage from 1994 teen births (3,873 births, 8.5%). This was the third consecutive year of increase in percent of births to teenage mothers. Teen births had peaked at 13.0% in 1975, declined annually to a low of 8.0% in 1992, and began rising in 1993. Teen mothers accounted for 4.5% of all white non-Hispanic births, 19.1% of all black non-Hispanic births, and 23.1% of all births to Hispanic women, representing an increase from the 1994 level for white non-Hispanics and decreases for the other two groups.

Of the eight towns with 1,000 or more births, six exceeded the state percentage (8.6%) of births to teens. They were: Hartford, 25.9% (down from 28.3% in 1994, but still the highest in the state); Bridgeport, 18.9%; New Britain, 17.5%; New Haven, 17.3%; Waterbury, 16.1%; and Danbury, 9.2%. This marked the first time in this decade that Danbury's teen birth percent exceeded that of the state. These six towns accounted for more than half (50.2%) of all births to teenage mothers, but less than one-fourth (23.2%) of all births in the state (Table 4). The remaining two towns with 1,000 or more births, Norwalk and Stamford, were below the state percentage for teen births, with 6.9% and 6.2%, respectively (Table 4).

Prenatal Care

Initiation of Prenatal Care

Of live births for which the date of entry into prenatal care was known, 87.7% of mothers began prenatal care during the first trimester of pregnancy (down from 89.1% in 1994), 9.8% during the second trimester, and 2.1% in the third trimester. An additional 140 women (0.3%) received no prenatal care. Trimester of initiation of prenatal care was unknown for 7.7% of total births.

The percentages for black non-Hispanic and Hispanic mothers were both about three times that for white non-Hispanics, that is, 23.3%, 24.9%, and 8.1% respectively. The values for all but black non-Hispanics, which fell 0.1%, were higher than in the prior year.

Of the eight towns with 1,000 or more births, only one, Danbury, did not exceed the state value for percentage of women who had late or no prenatal care (7.1%). The values for the other seven towns were: Waterbury, 32.6%; New Britain; 24.2%; New Haven, 22.7%; Hartford, 18.8%; Stamford, 18.6%; Bridgeport, 18.0%; and Norwalk, 17.7% (Table 4). Except for Stamford, which was unchanged, the 1995 rates for these towns all were higher than in 1994; most notably, the New Britain rate more than doubled (up from 10.8%). These seven towns accounted for 46.9% of births to women who received late or no prenatal care but only 27.7% of total resident births.

Adequacy of Prenatal Care

Of births for which adequacy of prenatal care could be determined, 83.5% had adequate care (down from 84.3% in 1994), 15.6% had intermediate care, and 0.9% had inadequate care (i.e., 16.5% received non-adequate care). Adequacy of prenatal care was unknown for 11.5% of total births (Table 3). This marks the first decline since 1989, when adequacy of prenatal care was first published in the Connecticut *Registration Report*.

Compared to 1994, percentages of non-adequate care were higher for white non-Hispanics and lower for black non-Hispanics and Hispanics. Still, women in the two minority groups were more than twice as likely as white non-Hispanics to receive non-adequate care. (See Appendix III, *Glossary* for definition of "adequacy of prenatal care.")

Of the eight towns with 1,000 or more births, one town, Danbury, was below the state percentage for non-adequate care (8.1%, up from 7.9% in 1994), while the other seven towns had percentages greater than the state's. Compared to 1994, the rates for three towns decreased: Hartford, 23.1% (down from 23.9%); Bridgeport, 23.3% (down from 28.6%); and Norwalk, 20.2% (down from 21.7%). In contrast, the values for four towns were higher than in 1994: Waterbury, 35.4% (up from 33.3%); New Britain, 33.3% (up from 20.5%); New Haven, 29.9% (up from 29.2%); and Stamford, 22.2% (up from 21.7%). Levels of non-adequate care in Bridgeport and Hartford fell to their 10-year lows in 1995, whereas non-adequate care in New Britain reached its 10-year high. The seven towns that exceeded the state value accounted for 42.0% of births to Connecticut women who received non-adequate prenatal care but only 27.7% of total resident births.

Tobacco Use during Pregnancy

In 1995, 4,090 births (10.5%) were to mothers who used tobacco during pregnancy (Table 3) [5]. This is somewhat lower than the comparable figure for U.S. births in 1995, (13.9%) [5].

Commenting on the U.S. smoking figures, the National Center for Health Statistics (NCHS) stated that "levels of maternal smoking based on the birth certificate are generally consistent with those recently reported from the National Pregnancy and Health Survey" [6]. This suggests that lower percentages in Connecticut may simply be due to better maternal health and not to underreporting. Tobacco use among Connecticut mothers included 10.4% of births to white non-Hispanics, 13.0% to black non-Hispanics, and 9.0% to Hispanics.

Alcohol Use during Pregnancy

In 1995, 522 births (1.3%) were to mothers who used alcohol during pregnancy (Table 3). This is close to the comparable figure reported for U.S. births (1.5%) [5]. Unfortunately, according to NCHS, alcohol use during pregnancy is "clearly underreported on the birth certificate" [7]. While underreporting is also likely in the Connecticut birth records, these data can be useful in assessing relative risks at the community level. The data do show a clear pattern of elevated risk of low birthweight among mothers consuming alcohol during pregnancy. Black non-Hispanics were three times more likely than Hispanics or white non-Hispanics to use alcohol during pregnancy (3.2%, 1.0%, and 1.1%, respectively).

FETAL DEATHS

Fetal deaths (stillbirths) are deaths to fetuses after 20 or more weeks of gestation. There were 285 resident fetal deaths in 1995, for a statewide rate of 6.4 per 1,000 live births (Table 2A), a decrease from 298 deaths (6.5 per 1,000) in 1994. Of fetal deaths with known sex, 151 (53.9%) were male and 129 (46.1%) were female (Table 5). Just under ten percent of the fetal deaths were of multiple plurality (Table 5); this is more than three times the proportion of live births of multiple plurality (3.1%) (Table 3). The percent distribution of fetal deaths by mother's age was roughly comparable to that of live births by mother's age for all age groups except "40-44 years," which had almost double the percentage of stillbirths as live births (Table 5). The fetal death rate for blacks (10.4/1,000 live births) was 73.3% higher than that for whites (6.0); the rate was not calculated for Hispanics because of under-reporting of ethnicity on fetal death certificates. Ethnicity was unknown for 63 of the fetal deaths (22.1%).

Town of Residence

Among the eight towns with 1,000 or more births, five had higher fetal death rates than the 1995 state rate of 6.4 per 1,000 live births (Table 2A). They were: New Haven, 10.8 (down from 12.1 in 1994); Hartford, 7.8 (down from 10.9); Waterbury, 11.4 per 1,000 (up from 9.9); New Britain, 10.8 (up from 8.6); and Bridgeport, 9.3 (up from 8.3). Danbury matched the state rate (6.4, down from 8.9), and Norwalk was below the state rate (6.2, up from 5.3). The rate for Stamford could not be calculated because there were less than 5 fetal deaths. These eight towns accounted for 38.2% of total fetal deaths and 30.2% of resident live births in the state.

Low Birthweight and Premature Delivery

More than eight of every ten resident fetal deaths (84.8%) were of low birthweight (<2,500 grams), and 72.1% were of very low birthweight (<1,500 grams) (Table 5). The percent fetal deaths with low birthweight was uniformly high for mothers of white race, black race, and Hispanic ethnicity. Overall, 84.9% of the resident fetal deaths were delivered prematurely (<37 weeks of gestation) (Table 5).

Leading Causes of Fetal Death

The three leading causes of fetal death for all races in 1995 were the same as in previous years: 1) "other and ill-defined conditions originating in the perinatal period" (113 deaths); 2) "fetus affected by complications of placenta, cord, and membranes" (54 deaths); and 3) "disorders relating to short gestation and unspecified low birthweight" (37 deaths) (Table 6). These categories are based on the standard groupings used by the National Center for Health Statistics [9]. The first leading cause of death was the same regardless of race or Hispanic ethnicity, whereas there was racial and ethnic variation among the second and third leading causes of death (Table 6).

INFANT DEATHS

In 1995 there were 322 resident infant deaths (down from 364 in 1994). The overall infant mortality rate was 7.3 per 1,000 live births, 7.6% lower than the 1994 rate of 7.9 per 1,000 but still higher than the 1993 rate (7.1 per 1,000). The neonatal mortality rate, based on 239 deaths to infants less than 28 days old, was 5.4 deaths per 1,000 live births, down from 5.8 in 1994. About three out of four infant deaths (74.2%) occurred during the neonatal period. The postneonatal mortality rate (based on 83 deaths to infants 28 days to 364 days old) was 1.9 deaths per 1,000 live births, down 13.6% from 2.2 in 1994 (Table 2A). As noted below, there was considerable variation in infant mortality rates by race and by town of residence.

Infant's Race

Infant mortality rates were calculated using two race-specific components: births, which reflect the race of the *mother*; and deaths, which reflect the race of the *infant*. In 1995, infant mortality rates again varied conspicuously by race, with disproportionate deaths to black infants; blacks accounted for 22.4% of resident infant deaths, but only 12.0% of total resident births (Table 2B). There were 245 deaths to infants of white race, for a rate of 6.7 per 1,000 live births (the same as the 1994 rate), 72 deaths to infants of black race, for a rate of 13.6 per 1,000 (down 28% from 18.9 in 1994), and 4 deaths to infants of other races. There also were 42 deaths to infants of Hispanic ethnicity; this mortality rate was not calculated, however, because of considerable under-reporting of Hispanic ethnicity on infant death certificates [10]. Ethnicity was unknown for 21 infant deaths (Table 2B).

Town of Residence

In 1995, infant deaths occurred to residents of 91 Connecticut towns. The five following towns reported 10 or more resident infant deaths (Table 2A). Bridgeport (7.1 deaths per 1,000 live births, 16 deaths) dropped 52.6% from the 1994 rate; Hartford (15.6 per 1,000, 36 deaths), decreased by 20.0%; and New Haven (13.0 per 1,000, 24 deaths) decreased 4.4%. In Waterbury, the infant death rate rose 24.0% to 10.3 per 1,000 (18 deaths); and the New Britain rate rose 13.9% to 9.8 per 1,000 (10 deaths). Together, these towns accounted for 32.3% of infant deaths but only 20.7% of resident births. A total of 10 towns had double-digit infant death rates in 1995.

Leading Causes of Infant Death

Since 1991, the classifications for leading cause of infant death in Connecticut have followed the standard groupings used by the National Center for Health Statistics [9]. Based on these groupings, the top three leading causes of infant death among all Connecticut residents in 1995 were: 1) "congenital anomalies;" 2) "disorders relating to short gestation and unspecified low birthweight;" and 3) "sudden infant death syndrome" (Table 8). The rankings of leading causes varied, however, by racial and ethnic subgroup, as shown below.

**Rank order of leading causes of infant death by infant's race and Hispanic ethnicity,
Connecticut, 1995.**

Cause of Death	Race			
	All	White	Black	Hispanic
Congenital anomalies	1	1		1
Disorders relating to short gestation or unspecified low birthweight	2	2	1	2
Newborn affected by maternal complications of pregnancy*			3	3
Newborn affected by complications of placenta, cord, membranes			3	
Sudden infant death syndrome	3		2	3

* Includes incompetent cervix, premature rupture of membranes, oligohydramnios, polyhydramnios, ectopic pregnancy, multiple pregnancy, maternal death, malpresentation before labor, and spontaneous abortion.

DEATHS (All Ages)

There were 29,438 deaths to Connecticut residents in 1995, the highest number in the history of the state. The crude death rate was 9.0 deaths per 1,000 population, up slightly from 8.9 in 1994 (Table 2A). The crude death rate has been rising annually since 1990 and in 1995 reached its highest level since 1968. Total resident deaths were determined by age of decedent for each sex, race, and ethnicity (Table 9). There were 16,862 deaths to persons aged 75 years and over, representing 57.3% of total resident deaths in 1995.

Of total resident deaths, 14,375 (48.8%) were males and 15,063 (51.2%) were females; 92.5% were of white race, 7.0% were of black race, and 2.7% were of Hispanic ethnicity (Table 9). About 7.2% more white females than white males died. In contrast, deaths to black males outnumbered those to black females by 26.3%, and deaths to Hispanic males surpassed those to Hispanic females by 77.6% (Table 9). Twelve decedents were of unknown race, and 943 were of unknown ethnicity (Table 2B, footnote 1).

All Causes of Death

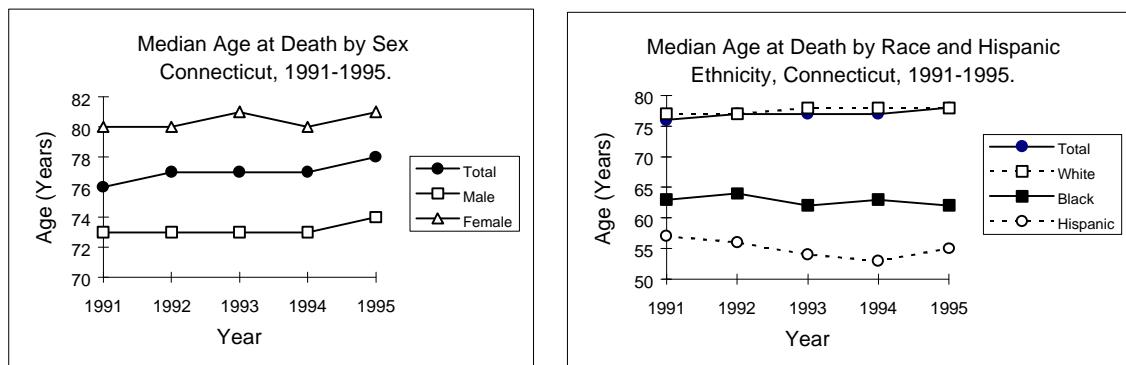

Town of Residence

Four towns reported 1,000 or more deaths in 1995 (Table 2A). Each had a crude death rate above the state rate: Waterbury, 10.7 per 1,000; New Haven, 10.0 per 1,000; Hartford, 9.4 per 1,000; and Bridgeport, 10.2 per 1,000. Among Connecticut's 169 towns, Burlington had the lowest crude death rate (3.5 per 1,000) and Essex had the highest (16.2 per 1,000).

Median Age at Death

The median age at death (see Appendix III, *Glossary*, for definition) was 78 years for both sexes combined, 74 years for males, and 81 years for females [11], representing an increase of one year over the 1994 median age at death for each group (see illustration below). Greater variation in median age at death existed by race and ethnicity. In 1995, the median age at death for Hispanics increased by two years to 55 years, following annual declines since 1991. The median age at death for blacks decreased by one year to 62 years, and the value for whites was 78 years (unchanged since 1993).

Median age at death by sex and race/ethnicity, Connecticut, 1991-1995.

Leading Causes of Death

The five leading causes of death in 1995 for persons of all ages and independently within each age and sex group are shown in rank order in Table 10. By proportional share of total deaths, they were: 1) "diseases of the heart;" 2) "malignant neoplasms;" 3) "cerebrovascular disease;" 4) "chronic obstructive pulmonary disease" (COPD); and 5) "pneumonia and influenza." These leading causes have been the same since 1989, with some alternation in rank order between COPD and pneumonia and influenza.

Age and Sex

Total deaths by age and the leading cause of death by age and sex are summarized in the table below.

First-ranked leading cause of death by age and sex, Connecticut, 1995.

Age	Sex			Total Deaths by Age ^a	
	Both	Male	Female	No.	%
<1	Congenital anomalies	Congenital anomalies	Congenital anomalies	322	1.1
1-4	Unintentional injuries	Unintentional injuries	Congenital anomalies	53	0.2
5-9	Unintentional injuries	Unintentional injuries	b	25	0.1
10-14	Unintentional injuries	Unintentional injuries	Unintentional injuries	47	0.2
15-19	Unintentional injuries	Unintentional injuries	Unintentional injuries	125	0.4
20-24	Unintentional injuries	Unintentional injuries	Unintentional injuries	170	0.6
25-34	Unintentional injuries	Unintentional injuries	HIV infection	653	2.2
35-44	HIV infection	HIV infection	Malignant neoplasms	1,188	4.0
45-54	Malignant neoplasms	Diseases of the heart	Malignant neoplasms	1,628	5.5
55-64	Malignant neoplasms	Malignant neoplasms	Malignant neoplasms	2,622	8.9
65-74	Malignant neoplasms	Malignant neoplasms	Malignant neoplasms	5,742	19.5
75-84	Diseases of the heart	Diseases of the heart	Diseases of the heart	8,797	29.9
85+	Diseases of the heart	Diseases of the heart	Diseases of the heart	8,065	27.4
All ages	Diseases of the heart	Diseases of the heart	Diseases of the heart	29,437 ^a	100.0

^a Total includes one death of unknown age.

c Unintentional injuries and malignant neoplasms each caused four deaths in this group.

Age <1 Year. (See INFANT DEATHS, p. 14.)

Ages 1-34 Years. The age groups within the 1-34 year interval accounted for 1,073 deaths, or 3.6% of total deaths. "Unintentional injuries" was the leading cause of death for males and for both sexes combined within the six age groups after infancy (1-4 through 25-34 years), and for females in the age cohorts from 10 to 24 years. Within this category, "motor vehicle accidents" claimed the most lives. In the age group 25-34, "HIV infection" was again the leading cause of death of females.

Ages 35-44 Years. The 35-44 year age interval accounted for 1,188 deaths, or 4.0% of total deaths. "HIV infection" remained the leading cause of death in this age cohort for males and both sexes combined. "Malignant neoplasms" was the leading cause of death of females aged 35-44. "Lung cancer" caused the most cancer deaths of males and both sexes combined, and "female breast cancer" took the most lives of women in this group.

Ages 45-74 Years. The next three consecutive age groups, 45-54, 55-64, and 65-74, accounted for 9,992 deaths, or 33.9% of total deaths in 1995. "Diseases of the heart" was the leading cause of deaths to males aged 45-54 for the third consecutive year, whereas "malignant neoplasms" remained the leading cause of deaths to males between the ages of 55 and 74 and to females and both sexes combined in all three age cohorts. "Lung cancer" was the most frequent cause of cancer deaths in males and both sexes combined in the 45-to-74-year age cohorts and in females aged 50-74, overtaking "female breast cancer" in the 50-54 female age group. "Female breast cancer," however, still caused the most cancer deaths in women aged 45-49.

Ages 75+ Years. The two age groups above 75 years accounted for 16,862 deaths, or 57.3% of total deaths in 1995. Overall and for each sex cohort in the age groups 75-84 and 85+ years, the leading cause of death was "diseases of the heart." "Ischemic heart disease" was the largest component within this category, accounting for nearly six of every ten deaths.

Selected Causes of Death

Resident deaths from different causes by sex, age , and race/ethnicity are given in Table 9. The 15 selected causes of death discussed below comprise the top 14 leading causes plus "motor vehicle accidents," a subgroup of "unintentional injuries" that is particularly important to public health. These 15 categories also are the focus of the discussion of age-adjusted mortality rates (see next section and Appendix IV).

To provide a general indication of the population subgroups at elevated risk, the distributions of deaths by sex and age were examined and are discussed below.

Ratios of Deaths by Sex

Although deaths to males and females were about equal for most causes of death and "all causes" combined, the numbers by sex were disproportionate for certain causes (Table 9). As shown below, male and female counts differed by a factor of 1.5 or more for 7 of the 15 selected causes of death. Between 1990 and 1995, the male-to-female ratios did not vary

much for suicide (3.5-5.0), homicide (3.1-4.0), unintentional injuries (1.7-1.9), and motor vehicle accidents (2.0-2.4). During the same period, however, the ratio for HIV infection fell from 4.3 to 2.8, indicating an increase in female deaths relative to males.

Ratios of deaths for selected causes of death^a, Connecticut, 1995.
(M/F = male to female ratio; F/M = female to male ratio.)

Cause of death	Ratio (M/F)	Ratio (F/M)
ALL CAUSES	1.0	1.0
Suicide and self-inflicted injury	4.1	
Homicide and legal intervention	4.0	
Human immunodeficiency virus (HIV) infection	2.8	
Motor vehicle accidents	2.0	
Unintentional injuries	1.7	
Chronic liver disease and cirrhosis	1.5	
Cerebrovascular disease		1.7

^a See list of selected causes of death in Appendix IV.

Also, while deaths from "malignant neoplasms" were about equal for both sexes, deaths to males from bladder cancer outnumbered those to females by a factor of 2.8.

Variation also existed between sexes in different racial and ethnic groups. For "all causes" of death, deaths to white females and white males were within 7% of one another, whereas deaths to males exceeded deaths to females by 26.3% for blacks and 77.6% for Hispanics. Also, the disparity between male and female deaths from "HIV infection" was much smaller for blacks (1.9) than for whites (3.8) or Hispanics (3.6).

Age

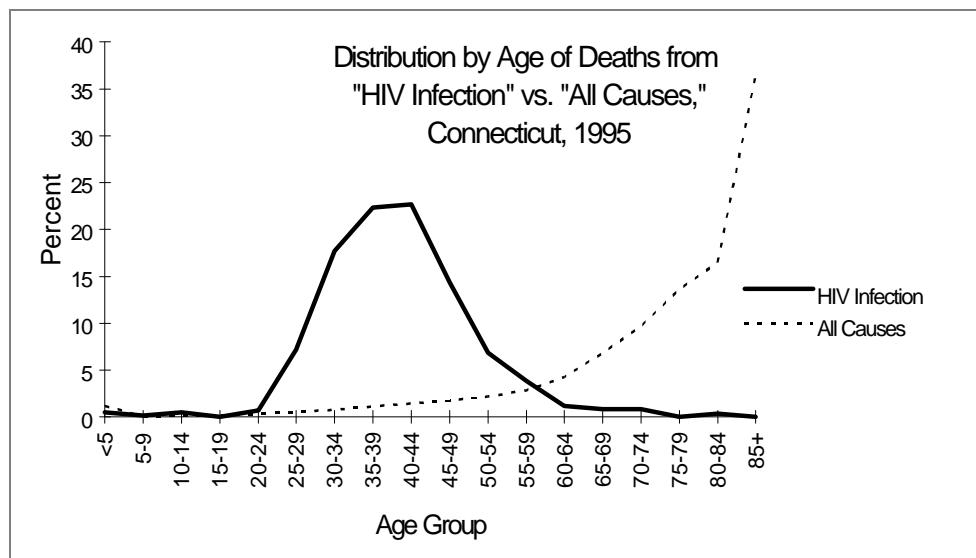

Distributions of deaths by age and sex for 15 selected causes of death and for "all causes" combined are given in Table 9. Total deaths from "all causes" rose progressively with age for both sexes, with deaths to males outnumbering deaths to females in all but the last two age groups (80-84 and 85+ years). Only about 23% of deaths occurred below age 65, whereas 49% of all deaths occurred at ages 65 to 84 years and another 27% after age 84. This pattern differed for males and females. The percentage of deaths to males under age 65 was 30%, whereas only 17% of females had died by age 65. After age 84 the converse was true, with the percentage of deaths to females (37%) exceeding that to males (18%).

The age profiles for the 15 selected causes of death were compared to the profile for "all causes," based on the percentage of deaths in each age group. Deaths due to "diseases of the heart," "septicemia," "nephritis and nephrotic disease," "chronic obstructive pulmonary disease," and "diabetes mellitus" had the same general profile as that for "all causes."

Relative to "all causes," the profiles for four of the selected causes were similar under age 85, but varied substantially for those 85 and over. The percentage of deaths among those aged

85+ was substantially lower for deaths due to “malignant neoplasms,” but higher for “cerebrovascular disease,” “pneumonia and influenza,” and “atherosclerosis.”

The age distribution for six of the selected causes of death differed markedly from that for “all causes.” Each had a higher percentage of deaths among young or middle-aged persons, with corresponding lower percents among the elderly. For “unintentional injuries,” “motor vehicle accidents,” “homicide and legal intervention,” and “suicide and self-inflicted injury” a greater concentration of deaths was noted among younger persons, beginning at ages 15-24 years. For deaths due to “HIV infection” and “chronic liver disease and cirrhosis,” there were higher proportions of deaths in the middle years, beginning at about age 30 and continuing through ages 54-64 (see illustration below). The age-at-death profile for “HIV infection” differed the most from that for “all causes.”

In general, the age profiles noted above for selected causes of death were similar for males and females when considered separately; however, the pattern of excess deaths due to “unintentional injuries” among younger persons was more exaggerated for males than for females.

AGE-ADJUSTED MORTALITY RATES FOR SELECTED CAUSES OF DEATH, 1970, 1980, AND 1985-1995

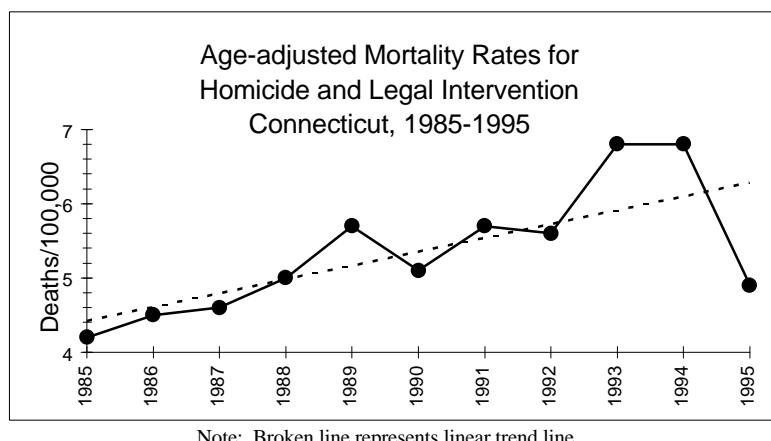

Trends in age-adjusted mortality rates (AAMRs) for 1970 and 1980 through 1995 for “all causes” and for 15 selected causes of death are shown in Appendix IV and Figures 2-6 (below). Age-adjusted rates, rather than crude rates, were used so that populations with

different age distributions could be compared. (See Appendix III, *Glossary*, for definitions of death rates.) Mortality rates were adjusted to the 1970 U.S. standard million population, using the direct method [12].

In 1995 the mortality rate from "all causes" decreased to 614.8 deaths per 100,000 population, down 1.2% from 622.0 in 1994. This decrease follows a two-year increase, and approaches the 25-year low of 612.3 deaths per 100,000 in 1992 (Fig. 3 and Appendix IV).

AAMRs That Decreased in 1995

The AAMR for "homicide and legal intervention" fell 27.9% to 4.9 deaths per 100,000, after several years of increasing rates. This was lowest rate since 1987, following an all-time high of 6.8 in 1993 and 1994, and represents the greatest percent decrease between 1994 and 1995 among the 15 selected causes of death for which AAMRs are given in Appendix IV. In 1995 all deaths in this category were homicides. The number of deaths in 1995, 149, also was the lowest since 1985.

Note: Broken line represents linear trend line.

In 1995 the AAMRs for three of the selected causes of death fell to 15-year lows. "Atherosclerosis" dropped 12.1% from the 1994 rate to 2.9 deaths per 100,000, representing a 84.2% decrease from a 1980 high of 18.4. "Diseases of the heart" decreased to 189.8 per 100,000, down 1.4% from the prior year and down 29.4% from the 1980 rate. "Malignant neoplasms" decreased 2.2% from the 1994 rate to 160.3 per 100,000; AAMRs for this cause of death have varied by less than 10% since 1980, and reached a high of 173.5 in 1985.

Other causes of death for which AAMRs decreased in 1995 were: "diabetes mellitus," down 4.4% to 13.0, following 3 years of increases; "pneumonia and influenza," down 7.1% to its lowest rate since 1983; "chronic obstructive pulmonary disease," down 2.5% following a 25-year high; and "cerebrovascular disease," down 0.9%.

AAMRs That Increased in 1995

The AAMR for "nephritis, nephrotic syndrome, and nephrosis" increased by 11.1%, from 6.3 to 7.0 deaths per 100,000. This represents the greatest percent increase between 1994 and 1995 among the 15 selected causes of death for which AAMRs are given in Appendix IV. AAMRs for this cause of death have consistently fluctuated between 5.3 and 7.1 per 100,000 since 1980. The 15-year high of 7.1 occurred in 1985.

 Unintentional injuries, chronic obstructive pulmonary disease (COPD),
 pneumonia & influenza, diabetes mellitus

* Age adjusted to 1970 U.S. standard population.

The AAMR for "HIV infection" has increased annually since mortality rates became available in 1987, and in 1995 was 14.2 deaths per 100,000 population, up 5.2% from the 1994 rate and 3.7 times the 1987 rate. The 1995 rise is attributable to an increase in HIV deaths to females; between 1994 and 1995, the AAMR for females increased by 25.4%, from 5.9 to 7.4 per 100,000 whereas the AAMR for males decreased slightly (0.5%), from 21.5 to 21.4 per 100,000 [13].

The AAMR for "unintentional injuries" rose for the fourth consecutive year, from 25.6 deaths per 100,000 population in 1994 to 27.2, an increase of 6.3%. Other rates that increased from 1994 to 1995 were: "motor vehicle accidents," up 5.0%; "chronic liver disease and cirrhosis," up 5.2%; "suicide and self-inflicted injury," up 1.1%; and "septicemia," up 6.4% from the prior year.

MARRIAGES

Marriage Rate

In 1995, there were 22,612 marriages in Connecticut (Table 2A). This is 108 (0.5%) fewer than in 1994, and is the lowest number registered in the past 25 years. The number of marriages in Connecticut has been declining since it reached an all-time high of 27,892 in 1988. The 1995 total represents a marriage rate of 13.8 persons per 1,000 population, down from 13.9 in 1994. The Connecticut marriage rate has been on a general decline since 1984, when it reached 17.2 per 1,000.

Town of Registration

Seven towns each registered more than 500 marriages in 1995 (Table 2A). They were Hartford (1,181), New Haven (933), Bridgeport (864), Stamford (776), Waterbury (699), Norwalk (548), and Danbury (528) (Table 2A). The most marriages were registered in Hartford, and none was registered in the town of North Stonington.

DIVORCES

Divorce Rate

There were 10,656 divorces in Connecticut in 1995, or about one for every two marriages, for a divorce rate of 6.5 persons per 1,000 population (Table 11). This is down from 6.9 in 1994, and represents the state's lowest rate and number of divorces since 1973. Divorces have been declining annually since 1992.

Minor Children

Of divorces for which number of children affected was known, 85.5% occurred in families with children under the age of 18, and at least 9,078 minor children were affected (Table 12) [14].

NOTES

- [1] According to the Connecticut General Statutes, "No certificate of birth shall contain any specific statement that the child was born in or out of wedlock or reference to illegitimacy of the child or to the marital status of the mother." The proxy "marital status" indicator, presumptive marital status, is based on the matching of surnames, with the classification "married" assigned under the following three conditions: i) if there is an exact match between the mother's and father's surnames; ii) if the father's and child's surnames match exactly, but the mother's name is missing; iii) if the child's surname is a hyphenated combination of the mother's and father's surnames (either entire surnames or portions of the parents' hyphenated surnames). This method of assessing marital status is probably of limited validity, because it assumes that married women who do not adopt their husbands' surnames are unmarried.

- [3] *Population Estimates by Town for Connecticut, 1990-1995*. Unpublished worksheet. Hartford: Connecticut Department of Public Health, Office of Policy, Planning and Evaluation.
- [4] In Connecticut, live births were not tabulated annually by age of mother until 1947, when only 21.3% of total live births were to women aged 30-34. Between 1947 and 1992, the greatest proportions of live births occurred to women aged 20-24 or 25-29. In 1993, for the first time in the state's recorded history, the 30-34 age group gave birth to the most babies of any 5-year age cohort. The age-specific birth rates for women in this group were, however, greater in 1947 than in 1993, 1994, or 1995 (122.5, 97.5, 98.4, and 100.3 births per 1,000 female population, respectively).
- [5] The elevated risk of poor pregnancy outcomes due to smoking is well documented (*see*: Ventura, S.J., J.A. Martin, S.C. Curtin, and T.J. Mathews. 1997. Report of final natality statistics, 1995. *Monthly Vital Statistics Report* 45(11, Suppl.): 1-84).
- [6] National Institute on Drug Abuse. 1996. *National Pregnancy and Health Survey--Drug use among women delivering live births: 1992*. National Institutes of Health. Rockville, Maryland: U.S. Department of Health and Human Services.
- [7] Buescher, P.A., K.P. Taylor, M.H. Davis, and J.M. Bowling. 1993. The quality of the new birth certificate data: A validation study in North Carolina. *American Journal of Public Health* 83(8): 1163-65.

- [8] Gestational age is calculated using the date of the last menstrual period (LMP) or the clinical estimate of gestational age, if the LMP is not available. Gestational age could not be determined for 2,048 (4.6%) of the resident births in 1995 (Table 3).
- [9] Some of the leading causes of death used by the NCHS for infant deaths are:

ICD-9 code(s)	Cause of death
480-487	Pneumonia and influenza
740-759	Congenital anomalies
761	Newborn affected by maternal complications of pregnancy
762	Newborn affected by complications of placenta, cord, and membranes
765	Disorders relating to short gestation and unspecified low birthweight
768	Intrauterine hypoxia and birth asphyxia
769	Respiratory distress syndrome
771	Infections specific to the perinatal period
798.0	Sudden infant death syndrome
E-800-E949	Unintentional injuries

The adoption of the NCHS classifications for ranking infant death allows readers to make comparisons with national statistics more easily. The standard cause-of-death categories used by NCHS for infants are different than those used for older age groups. (See, for example, "Table 33. Leading causes of death and numbers of deaths, according to age: United States, 1980 and 1993," in *Health, United States, 1995*, National Center for Health Statistics, Hyattsville, Maryland, Public Health Service, 1996, p. 10117-118.) Also, the NCHS classifications tend to be more narrow and specific than the categories used in prior Connecticut vital statistics reports. For example, the NCHS classification breaks the large category used in prior reports, "Conditions originating in the perinatal period" (ICD-9 codes 760-779), into smaller components, as noted in the table above and in Tables 8 and 10 of the present vital statistics report.

- [10] Analysis of 1989 infant mortality data from a linked birth-death file indicated under-reporting of Hispanic ethnicity by about 50% in standard, calendar-year tabulations.
- [11] *Median Age at Death for CT Residents, 1989-1995*. Unpublished tables. Hartford: Connecticut Department of Public Health, Office of Policy, Planning and Evaluation.
- [12] Age-adjusted mortality rates for 1970 and 1980-1995 were calculated using 10-year age intervals, following the direct method. (Fleiss, J.L. 1981. *Statistical Methods for Rates and Proportions*. New York: John Wiley & Sons, p. 224-247.)

The direct method of adjustment requires age-and sex-specific population figures. Population data for different time periods were obtained from different sources, as noted below.

- a) The 1970 rate denominators were published in the Connecticut *Registration Report* for 1970.

- b) The 1980 rate denominators were published in the Connecticut *Registration Report* for 1980.
- c) The denominators used for the years 1981-1989 were the intercensal estimates published in: U.S. Bureau of the Census, *Preliminary Intercensal Estimates of the Population of States: 1981-1989*, November 1, 1991. The U.S. Bureau of the Census has revised these intercensal figures using the 1990 MARS data. These final intercensal figures vary little from the preliminary figures; hence, the 1981-1989 AAMRs were not recalculated using the final figures. The final intercensal figures are available upon request from the CT Department of Public Health.
- d) The 1990 denominators are the modified age, race, and sex population counts published by the U.S. Bureau of the Census. (U.S. Bureau of the Census. 1990. *Age, sex, race and Hispanic origin information from the 1990 Census: A comparison of census results with results where age and race have been modified.* Publ. No. 1990 CPH-L-74.)
- e) The 1991-1995 denominators were calculated based on two components:
 - (i) Connecticut population estimates published by the Connecticut Department of Public Health; and (ii) age-sex population distributions for Connecticut published by the U.S. Bureau of the Census. The estimated Connecticut age-sex population counts were calculated by multiplying (i) and (ii), with appropriate rounding of the resulting figures.

Connecticut population estimates for 1991-1995 are given in:

- *Estimated Populations in Connecticut as of July 1, 1991.* Hartford: Connecticut Department of Health Services, Division of Health Surveillance and Planning, September, 1992.
- *Estimated Populations in Connecticut as of July 1, 1992.* Hartford: Connecticut Department of Public Health and Addiction Services, September, 1993.
- *Estimated Populations in Connecticut as of July 1, 1993.* Hartford: Connecticut Department of Public Health and Addiction Services, September, 1994.
- *Estimated Populations in Connecticut as of July 1, 1994.* Hartford: Connecticut Department of Public Health, Office of Policy, Planning and Evaluation, September, 1994.
- *Estimated Populations in Connecticut as of July 1, 1995.* Hartford: Connecticut Department of Public Health, Office of Policy, Planning and Evaluation, September, 1995.

The U.S. Census Bureau's estimated age-sex distributions of the Connecticut population are given in the following publications:

- Davis, S. *Estimates of the Population of States by Age, Sex, Race and Hispanic Origin: 1991.* U.S. Bureau of the Census, Population Division, 1994.

- Byerly, E. and K. Deardorff. *National and State Population Estimates: 1990-1994*. U.S. Bureau of the Census, Current Population Reports, p. 31-32. Washington, DC: U.S. Government Printing Office.
 - *Resident Population of the U.S. and States, by Single Year of Age and Sex: July 1, 1995 Estimates*. Population Estimates and Population Distribution Branches, U.S. Bureau of the Census.
- [13] *Connecticut Resident Deaths, 1995. Number of Deaths, Crude Mortality Rate, and Age-adjusted Mortality Rate for Selected Causes of Death by Sex of Decedent*. Unpublished worksheet. Hartford: Connecticut Department of Public Health, Office of Policy, Planning and Evaluation.
- [14] The 1995 estimates of children affected by divorce may be low, as information about children under 18 in the household was missing from 4,483 divorce records (42.1% of total).

Notes: " - " Represents the quantity zero.

a Rates are not calculated for less than 5 events due to the high degree of variability associated with these figures.

1. Live birth and death rates are per 1,000 population.

2. Fetal and infant death rates are per 1,000 live births.

3. Caution is advised when analyzing marriage statistics which are based on the number of events occurring in a town or county and may or may not reflect the county or town of residence of either party. There were 13 records where county was unknown.

Notes: " - " Represents the quantity zero.

1. Race and ethnicity are separate categories. Individuals identifying themselves as "Hispanic" can be of any race and are also counted in the race breakdown as either white, black, or other. Only the main components of race and ethnicity are displayed (unknown race, unknown ethnicity and non-Hispanic are omitted). Readers should not expect the race and/or ethnicity components to sum to the total number of events. Overall, race was unknown for 946 births, 12 deaths and 3 fetal deaths. Ethnicity was unknown for 2,412 births, 943 deaths (21 infant deaths) and 63 fetal deaths.
2. "Other" refers to the race category "Other Races".

Notes: " - " Represents the quantity zero.

- a. Percents based on fewer than 5 events are not calculated due to the high degree of variability associated with these figures. The denominator in each percent calculation excludes records with missing information.
- 1. See the Glossary for the full definition of presumptive marital status.
- 2. Initiation of prenatal care refers to the pregnancy stage in which the first prenatal visit occurs (see Glossary).
- 3. Adequacy of prenatal care is based on a modified Kessner Index (see Glossary).
- 4. Percent premature is defined as births of less than 37 weeks per birth of known gestational age.
- 5. At the top of this table, under Mother's Race/Ethnicity, five mutually exclusive race/ethnicity groups are listed. Since the unknown ethnicity count is not given, the figures provided sum to less than the total All Races count. There were 2,412 records with unknown ethnicity. After the top section of this table less detail is provided. Only the main components of the race/ethnicity categories are displayed.
- 6. "Live Birth Order" identifies the birth order of each child based on the current pregnancy and all previous pregnancies.

Notes: " - " Represents the quantity zero.

- a. Percents are not calculated for less than 5 events due to the high degree of variability associated with these figures. The denominator in each percent calculation excludes records with missing information.
- 1. Very low birthweight is defined as an infant weighing less than 1,500 grams at birth.
- 2. Low birthweight is defined as an infant weighing less than 2,500 grams at birth.
- 3. Late prenatal care is defined as prenatal care beginning in the second or third trimester of pregnancy.
- 4. Non-adequate prenatal care is defined as intermediate or inadequate prenatal care based on a modified Kessner Index.
- 5. At the top of this table, under Mother's Race/Ethnicity, five mutually exclusive race/ethnicity groups are listed. Since the unknown ethnicity count is not given, the figures provided sum to less than the total Connecticut count. There were 2,412 records with unknown ethnicity. After the top section of this table less detail is provided. Only the main components of the race/ethnicity categories are displayed.

Hispanic		1	1	-	-	-	-	-	-	a	a	1	-	a

NOTES: " - " Represents the quantity zero.

- a. Percents based on fewer than 5 events are not calculated due to the high degree of variability associated with these figures.
- 1. Fetal deaths do not include deaths that occur prior to the 20th week of gestation (see Glossary).
- 2. Records where race or ethnicity is unknown are not displayed. Overall, there were three records with unknown race and 63 with unknown ethnicity.
- 3. Premature is defined as fetal deaths of less than 37 weeks per fetal death of known gestational age.

Notes: " - " Represents the quantity zero.

1. Race and ethnicity are separate categories. Individuals identifying themselves as "Hispanic" can be of any race and are also counted in the race breakdown as either white, black or other. Only the main components of race are displayed. Two components of ethnicity are also omitted (non-Hispanic and unknown ethnicity). Readers should not expect the race and/or ethnicity components to sum to the total number of events. "Other" refers to the race category "Other Races". In order to make this table more concise, counts for those of unknown race were omitted. Overall, there were 21 records with unknown ethnicity and 1 with unknown race.

Notes: " - " Represents 0 events.

1. For conciseness, only the main components of race and ethnicity are displayed. Consequently, the component race counts given (white and black) may sum to less than the All Races total. Counts for those of Hispanic ethnicity are displayed; however, figures for the two other ethnicity components (non-Hispanic and unknown ethnicity) are not displayed.

2. "All other infectious and parasitic diseases" includes the following ICD-9 cause-of-death classifications:

01 - 09 Intestinal infectious diseases	90 - 99 Syphilis and other venereal diseases
20 - 41 Zoonotic bacterial diseases and other bacterial diseases	100 - 104 Other spirochetal diseases
45 - 49 Poliomyelitis and other non-arthropod-borne viral diseases of central nervous system	110 - 118 Mycoses
50 - 57 Viral diseases accompanied by exanthema	120 - 129 Helminthiases
60 - 66 Arthropod-borne viral diseases	130 - 136 Other infectious and parasitic diseases
70 - 79 Other diseases due to viruses and chlamydiae	137 - 139 Late effects of infectious and parasitic diseases
80 - 88 Rickettsioses and other arthropod-borne diseases	

3. This category includes deaths resulting from accidents to watercraft causing submersion and drowning (E830), other accidental submersion or drowning in water transport accidents (E832) and accidental drowning and submersion (E910).

TABLE 10 (Continued)

Connecticut Residents, 1995:
Top Five Leading Causes of Death¹ by Age and Sex

- Notes:**
1. The leading causes of death are ranked within each age and sex category. Cause of death subgroup counts and rates are also provided where major cause of death groups are ranked in the top five. The causes are listed in rank order using the both sexes column first, followed by the male and the female columns.
 2. Age-specific death rates and crude death rates are calculated per 100,000 population. The 1995 population counts presented in Table 1 were used as the denominators for these rates. Rates for persons under 1 year of age are an exception. For this group, rates were calculated per 1,000 live births. Denominators for the 1 to 4 age group were derived by subtracting 1995 resident births of known sex from the 0 to 4 age group population figure. Crude death rates for persons of all ages are provided at the end of Table 10. Since this last section of Table 10 is not age-specific, the rate column is labeled "Crude Death Rate per 100,000." Age of decedent was unknown for one record.
 3. "All other infectious and parasitic diseases" includes the following ICD-9 cause-of-death classifications:

01 - 09	Intestinal infectious diseases	90 - 99	Syphilis and other venereal diseases
20 - 41	Zoonotic bacterial diseases and other bacterial diseases	100 - 104	Other spirochetal diseases
45 - 49	Poliomyelitis and other non-arthropod-borne viral diseases of central nervous system	110 - 118	Mycoses
50 - 57	Viral diseases accompanied by exanthema	120 - 129	Helminthiases
60 - 66	Arthropod-borne viral diseases	130 - 136	Other infectious and parasitic diseases
70 - 79	Other diseases due to viruses and chlamydiae	137 - 139	Late effects of infectious and parasitic diseases
80 - 88	Rickettsioses and other arthropod-borne diseases		

* There may be age and sex categories with fewer than 5 listed ranks. This is because there were either fewer than five leading causes or because causes with less than two reported deaths are not presented. Causes of death with the same number of deaths have the same rank within the category. Unranked counts in parentheses "()" are provided in order to allow readers to examine the count distribution by gender.

TABLE 11
Connecticut Divorces, 1995:
Number of Divorces by County

County	Total
Connecticut, Total	10,656
Fairfield	2,283
Hartford	2,714
Litchfield	475
Middlesex	529
New Haven	2,633
New London	1,089
Tolland	526
Windham	403

APPENDICES

Appendix I

RATE DEFINITIONS

Age-specific birth rate	=	Number of live births in a specific age group Total resident population in specific age group	x 100,000
Age-specific death rate	=	Number of deaths in a specific age group Total resident population in specific age group	x 100,000
Crude birth rate	=	Number of resident live births Total resident population	x 1,000
Crude death rate	=	Number of resident deaths Total resident population	x 1,000
Divorce rate^a	=	Number of persons granted divorces Mid-year total resident population	x 1,000
Fetal death rate^b	=	Number of fetal deaths Number of live births	x 1,000
Infant death rate	=	Number of infant deaths Number of live births	x 1,000
Marriage rate^a	=	Number of persons married Mid-year total resident population	x 1,000

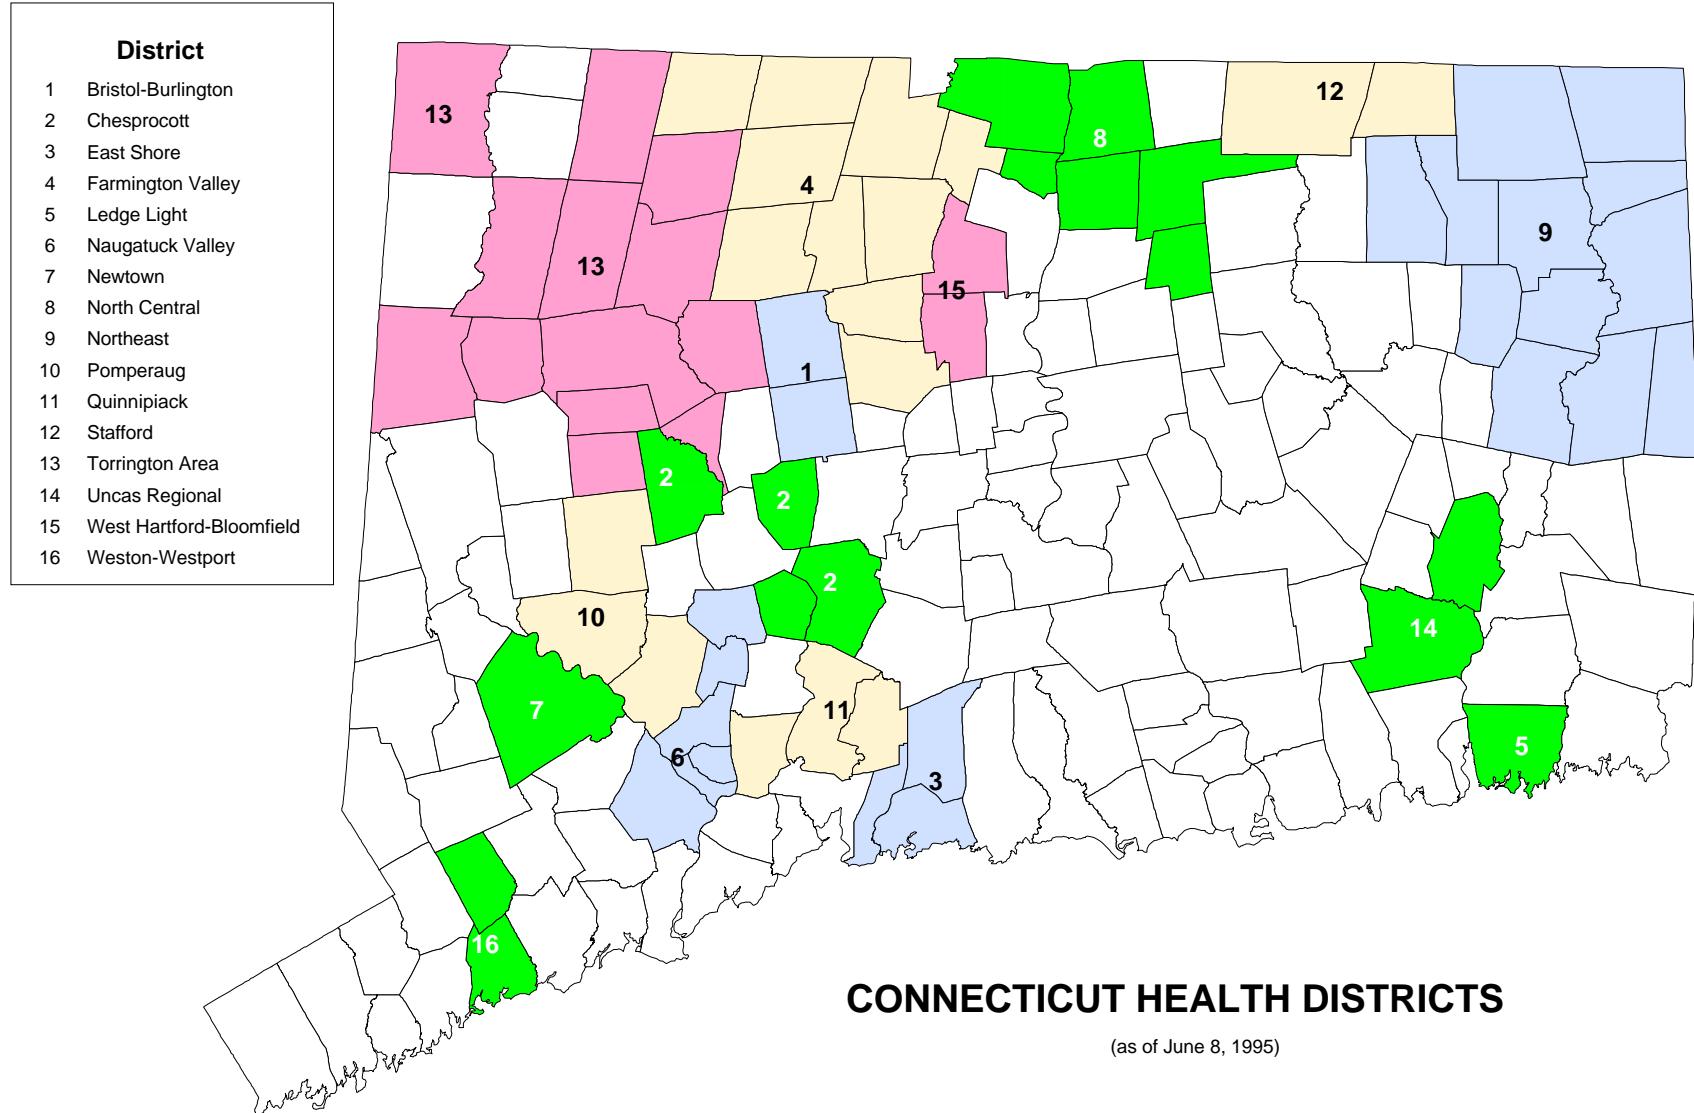

^a Marriage and divorce counts provided in the tables in this report refer to number of *couples*, not *individuals*, who married or divorced. To calculate the marriage or divorce *rates*, the marriage or divorce counts were multiplied by two.

^b This fraction is often referred to as a *ratio*, rather than a *rate*, because the denominator (live births) does not contain the numerator (fetal deaths).

Appendix II
HEALTH DISTRICT DEFINITIONS
USED IN 1995 REGISTRATION REPORT

Health District	Constituent Towns^a
Bristol-Burlington Health District	Bristol, Burlington
Chesprocott Health District	Cheshire, Prospect, Wolcott, Watertown
East Shore District Dept. of Health	Branford, East Haven, North Branford
Farmington Valley Health District	Avon, Barkhamsted, Canton, Colebrook, East Granby, Farmington, Granby, Hartland, New Hartford, Simsbury
Ledge Light Health District	City of Groton, Town of Groton
Naugatuck Valley Health District	Ansonia, Beacon Falls, Derby, Naugatuck, Seymour, Shelton
Newtown Health District	Town of Newtown, Borough of Newtown
North Central Health District	East Windsor, Ellington, Enfield, Suffield, Vernon, Windsor Locks
Northeast District Dept. of Health	Ashford, Brooklyn, Canterbury, Eastford, Hampton, Killingly, Plainfield, Pomfret, Putnam, Sterling, Thompson, Woodstock Oxford, Southbury, Woodbury
Pomperaug Health District	Hamden, North Haven, Woodbridge
Quinnipiack Valley Health District	Stafford (Stafford Springs Borough), Union
Stafford Health District	Bethlehem, Cornwall, Goshen, Harwinton, Kent, Litchfield , Morris, Norfolk, Salisbury, Thomaston, Torrington, Warren, Winchester
Torrington Area Health District	Montville, Norwich
Uncas Regional Health District	Bloomfield, West Hartford
West Hartford-Bloomfield Health District	Weston, Westport

^a Constituent towns are listed as of June 8, 1995.

Appendix III

GLOSSARY

Adequacy of prenatal care: *See* Kessner Index.

Age-adjusted death rate (Direct method): A summary of age-specific death rates, applied to a standard population (this report use the 1970 U.S. standard million) to calculate what rate would be expected if the selected population had the same distribution as the standard population. The total of expected deaths divided by the total of the standard population and multiplied by 100,000 yields the age-adjusted death rate per 100,000.

The 1970 U.S. standard million population distribution is shown below.

Age	Population	Age	Population
<5	84,416	50-54	54,643
5-9	98,204	55-59	49,077
10-14	102,304	60-64	42,403
15-19	93,845	65-69	34,406
20-24	80,561	70-74	26,789
25-29	66,320	75-79	18,871
30-34	56,249	80-84	11,241
35-39	54,656	85+	7,435
40-44	58,958	Total	1,000,000
45-49	59,622		

Age-specific birth rate: The number of live births to women in a specific age group per 1,000 females in the population in the same age group.

Age-specific death rate: The number of deaths in a specific age group per 1,000 population in the same age group.

Age-specific death rate: The number of deaths for a specific age group per 100,000 population in the same age group.

Birthweight: The first weight of a fetus or infant at time of delivery. This weight is usually measured during the first hour of life, before postnatal weight loss occurs.

Cause of death: The underlying cause of death determined to be the primary condition leading to death, based on the international rules and sequential procedure set forth for manual classification of the underlying causes of death by the National Center for Health Statistics and the World Health Organization (*International Classification of Disease, Ninth Revision*). (See also: "Underlying cause of death.")

Crude death rate: The number of deaths per 1,000 population. This rate should not be used for making comparisons between different populations when the age, race, and sexdistributions of the populations are different. (See "Age-adjusted death rate" and "Age-specific death rate.")

Divorce: The final legal dissolution of a marriage.

Ethnicity: See "Hispanic ethnicity."

Fetal death: Death prior to the complete expulsion or extraction from the mother of a product of conception, which has passed through at least the 20th week of gestation. The fetus shows no signs of life such as heartbeat, pulsation of the umbilical cord, or movement of voluntary muscles.

Gestational age: The number of completed weeks elapsed between the first day of the last normal menstrual period (LMP) and the date of delivery.

Health district: A local governmental entity consisting of two or more towns that is responsible for the public health of its constituent towns. (See Appendix II for a listing of the 16 health districts in existence in Connecticut as of June 8, 1995.)

Hispanic ethnicity: Refers to people whose origins are from Spain, the Spanish-speaking countries of Central America, South America, and the Caribbean, or persons of Hispanic origin identifying themselves as Spanish, Spanish-American, Hispanic, Hispano, Latino, and so on. In Connecticut, the birth, death, and fetal death certificates have a separate line item for the individual's Hispanic status, to attempt to distinguish Hispanic ethnicity from race. Individuals identifying themselves as "Hispanic" can be of any race, and are also counted in the race breakdown as either "white," "black," or "other."

Infant death: Death occurring to an individual of less than one year (365 days) of age, comprising the sum of *neonatal death* and *postneonatal death*.

Kessner Index (Modified): The Kessner Index is a composite indicator of the adequacy of prenatal care a mother receives during her pregnancy. Prenatal care is categorized as *adequate*, *intermediate*, or *inadequate* based on three items from the birth certificate: timing of the first prenatal visit; total number of prenatal visits; and length of gestation. The term, *non-adequate* prenatal care, which is the sum of the intermediate and the inadequate levels of care, is used in Table 4 of the present report.

The modified Kessner Index used in this report differs from the usual definition in that more extensive efforts have been made to minimize the amount of missing information. In addition, certain extreme values of gestational age, which may have resulted from the mother's inability to recall the date of the last menstrual period, have been redefined as "missing" (about 1% of the records). A more detailed definition of the Modified Kessner Index, describing the three index components and the methods used to calculate each, is available from the Connecticut Department of Public Health, Office of Policy, Planning and Evaluation.

Live birth: The complete expulsion or extraction from the mother of a product of conception, regardless of the duration of pregnancy; after such separation, shows signs of life (e.g., heartbeat, pulsation of the umbilical cord, or movement of voluntary muscles).

Live birth order: The number of children born alive to the same mother, including the current birth (first born, second born, third born, etc.).

Low birthweight: A birthweight of less than 2,500 grams (approximately 5 lbs., 8 oz.).

Median age at death: The age that falls exactly in the middle of the entire range of ages ranked in order from low to high, such that 50% of the deaths fall above it and 50% fall below it. If the number of deaths is even, a value halfway between the two ages nearest the middle is used.

Neonatal death: Death occurring to an infant less than 28 days of age.

Occurrence: Place of occurrence identifies where the vital event actually took place, regardless of the place of residence of the individual.

Plurality: The number of siblings born as the result of a single pregnancy; commonly expressed as *singleton* or *multiple*.

Postneonatal death: Death occurring to an infant aged 28 days to 364 days.

Premature: A live birth or fetal death that occurs before the completion of the 37th week of gestation.

Presumptive marital status: Because of statutory limitations, there is no "marital status" line item on Connecticut birth records. Marital status is inferred by comparing child's and parents' surnames. A birth is classified as occurring to a married couple if: 1) the parents' surnames are the same; or 2) if the child's and father's surnames are the same and the mother's current surname is missing in the birth certificate. A birth is classified as occurring to an unmarried couple if: 1) the father's name is missing; or 2) the parents' surnames are different.

Race: A population of individuals who identify themselves from a common history, nationality, or geographical place. When responses in the "race" line item on vital records are associated with the definition of Hispanic origin, they are re-coded to "white race," as described in the National Center for Health Statistics instruction manuals for coding vital records. Individuals identifying themselves as either "white," "black," or "other" race can be of any ethnic group. (See also "Hispanic ethnicity.")

Residence: The usual place of abode of the person to whom the vital event occurred. For births and fetal deaths, residence is defined as the mother's usual place of residence.

Teenage mother: A woman under 20 years of age on the date of delivery.

Trimester of pregnancy: One-third of the total gestation period of a full-term pregnancy, or 13 weeks per trimester. The "third trimester" classification comprises pregnancies of 27 or more weeks gestation. The weekly count begins on the first day of last menstrual period.

Underlying cause of death: The disease or injury that initiated the sequence of events leading directly to death, or the circumstances of the accident or violence that produced the fatal injury.

Very low birthweight: A birthweight of less than 1,500 grams (approx. 3 lbs., 5 oz.).

Appendix IV

AGE-ADJUSTED MORTALITY RATES FOR SELECTED CAUSES OF DEATH 1970 AND 1980-1995

(Deaths per 100,000 population^a)

Cause of Death	Year of Death

^a Mortality rates were adjusted to the 1970 U.S. standard million population, using the direct method.

^b COPD = Chronic obstructive pulmonary disease (emphysema, chronic bronchitis, etc.).

^c HIV = Human Immunodeficiency Virus. Cause-of-death codes for HIV infection were not available until 1987.
